for

CLONING AND CHARACTERIZATION OF THE flba GENE OF H. PYLORI,

PRODUCTION OF AFLAGELLATE STRAINS

CLONING AND CHARACTERIZATION OF THE FIDA GENE OF H. PYLORI. PRODUCTION OF AFLAGELLATE STRAINS

Helicobacter pylori (also designated 5 H. pylori) is a Gram-negative bacterium which, to date, has been found exclusively on the surface of the mucosa of the stomach in man.

In common with most bacteria, H. pvlori is sensitive to a medium which is at acid pH but, never-10 tholens, is able to tolerate acidity in the presence of physiological concentrations of urea (Marshall et al. (1990) Gastroenterol. 99: 697-702). By hydrolysing the urea to form carbon dioxide and ammonia, which are released into the microenvironment of the bacterium, the H.pylori urease enables the bacterium to survive in acidic environment of the stomach. Recently, studies carried out on animal models have provided data suggesting that the urease is an important factor in the colonization of the gastric mucosa (Eaton et al. (1991) Infect. Immun. 59: 2470-2475). The urease is also suspected of causing injury, either directly or indirectly, to the gastric mucosa.

Currently, Helicobacter pylori (H. pylori) recognized as being the etiological agent of antral gastrites, and appears to be one of the cofactors required for the development of ulcers. Furthermore, it

25

30

appears that the development of gastric carcinomas may be associated with the presence of <u>H. pylori</u>.

In order to develop novel sensitive and specific means for detecting in-vitro infections due to bacteria of the <u>Helicobacter pylori</u> species, the inventors have been taking an interest in the system for regulating the mobility of these bacteria.

With this aim in view, they have been interested in different modifications of the <u>H.pvlori</u> strains, modifications which did not affect the recognition of these bacteria by sera from infected patients but which nevertheless rendered it possible to avoid obtaining reactions of the "false positive" type, in particular with bacteria of the Campylobacter family, for example <u>Campylobacter iciuni</u>.

Furthermore, the inventors observed that it was possible, if need be, for the modified bacteria which were obtained to be employed in constructing immunogenic compositions or compositions used for vaccination. In this respect, the invention proposes, in particular, live attenuated bacterial strains.

In a first step, the inventors identified and isolated the gene flbA which is involved in the regulation of the biosynthesis of the flagella of H.pvlori and, as a consequence, in the regulation of the mobility of the bacterium. The biosynthesis of the flagella comprises synthesizing flagellins A and B and synthesizing the shooth. The flbA gene regulates both the synthesis of flagellins A and B and the synthesis of the sheath which contains these flagellins. The inventors established that the flbA gene was also important in that it regulated the biosynthesis of the anchoring protein of the bacterium, also termed the "hook".

35 The invention therefore relates to a nucleotide sequence from the flbA gene regulating the biosynthesis of the proteins of the Holicobacter pylori flagella, characterized in that it is able to hybridize, under conditions of high stringency, with a probe

25

35

corresponding to a nucleotide fragment from <u>H.bylori</u> which has been amplified using two oligonucleotides having the following sequences:

OLF1ba-1: ATGCCTCGAGGTCGAAAAGCAAGATG

5 OLF1bA-2: <u>GAAATCTTCATACTGGCAGCTCCAGTC</u>, or able to hybridize, under conditions of high stringency, with those oligonucleotides.

Such a sequence can be obtained by the steps of:

- screening a genomic library containing the chromosomal DNA of an <u>H.pylori</u> strain with a probe corresponding to a nucleotide fragment from <u>H.pylori</u> which has been amplified using two oligonucleotides having the following sequences:

OLF1bA-1: ATGCCTCGAGGTCGAAAAGCAAGATG

OLF1bA-2: <u>GAAATCTTCATACTGGCAGCTCCAGTC</u>, or able to hybridize, under conditions of high stringency, with these oligonucleotides,

- recovering the DNA sequences which hybridize 20 with the said probe,
 - subcloning the DNA sequences which have been obtained in an appropriate vector of the plasmid type and selecting those modified vectors which hybridize, under conditions of high stringency, with the probe corresponding to the DNA fragment from #_pylori which has been amplified using oligonucleotides OLFlbA-1 and OLFlbA-2,
 - sequencing the DNA fragments contained in the plasmid vectors which hybridize with the abovementioned probe and determining the open reading frame contained in these fragments.

Advantageously, these DNA fragments will be used to reconstitute the coding sequence of the flbA gene, corresponding to an open reading frame comprising approximately 2196 nucleotides.

The genomic library containing the chromosomal DNA of <u>H. pylori</u> can be obtained from any <u>H. pylori</u> strain. A cosmid library may also be prepared from the chromosomal DNA of <u>H. pylori</u>.

10

30

35

An example of a strain which can be used for constructing this library is the strain N6, which was deposited in the NCIMB on 25 June 1992 under No. NCIMB40512.

The two oligonucleotide primers which are used for preparing the probe which is intended for hybridizing the sought-after DNA which is present in the <u>H.pvlori</u> DNA library are selected from the conserved regions of the various proteins of the LcrD/FlbF family.

The two oligonuclastide primers, OLFlbA-1 and OLFlbA-2, enabled a fragment to be amplified which was usable as a probe and which was of 130 base pairs, having the following sequence:

ATG CCA GGA AAG CAA ATG GCG ATT GAT GCG GAT TTA AAT TCA
GGA CTT ATT GAT GAT AAG GAA GCT AAA AAA CGG CGC GCC
CTA AGC CAA GAA GCG GAT ITT TAT GGT GCG ATG GAT GGC GCG
TCT AAA TTT

The conditions of high stringency referred to above are the following: the hybridization is carried out at 42°C in the presence of 50% formamide in a 2×SSC buffer containing 0.1% SDS (1×SSC corresponds to 0.15 M NaCl plus 15 mM sodium citrate - pH 7.0). The washings are carried out at 68°C, for example twice during a period of one hour, using 2×SSC plus 0.1% SDS.

A nucleotide sequence which is particularly interesting in accordance with the invention is the sequence of the <u>flbA</u> gene corresponding to the sequence of nucleotides depicted in Figure 2, or to a nucleotide sequence which hybridizes, under conditions of high stringency, with the abovementioned sequence.

According to another embodiment of the invention, the nucleotide nequence which is the subject-matter of the present application is characterized in that it encodes a protein having the amino acid sequence depicted in Figure 2 or an amino acid sequence possessing the name regulatory properties, with regard to the biosynthesis of the flagellar proteins of H.pylori, as the abovementioned sequence.

30

The invention also relates to a nucleotide sequence which corresponds to the previous definitions and which is modified by deletion, substitution or insertion of bases or of a fragment of a nucleotide sequence, such that:

- either the <u>flbA</u> gene is no longer expressed in a host cell,
- or the expression of the <u>flbA</u> gene in a host cell does not enable the A and B flagellins or the sheath which contains them to be biosynthesized and, if this is the case, does not enable the <u>H.pylori</u> anchoring protein or the hook, to be synthesized.

modification to which the nucleotide The sequence of the invention is subjected should be such that it is irreversible and, in particular, that it 15 remains irreversible when this sequence is recombined with the flbh gene which is present in a bacterium which is transformed with a nucleotide sequence which is modified in this manner. This recombination is, for example, of the "double crossing over" type. Pre-20 ferably, the modification of the nucleotide sequence should not involve any substantial modification - after replacement, by this modified sequence, of the corresponding fragment of the normal flbA gene in a given H.pylori strain - of the functions of the neighbouring 25 genes.

Also included within the scope of the invention are nucleotide sequences which constitute a fragment of the <u>flbA</u> gene meeting the above criteria. As examples, fragments which are the subject-matter of the invention consist of at least 6 nucleotide sequences, preferably at least 50, if not at least 100 nucleotides.

Such fragments are, for example, selected either on account of their specific flbA gene character or because they belong to conserved regions of several genes encoding proteins of the LcrD/FlbF family.

According to another embodiment, the invention is also directed towards the fragments of the flbA gene which are delimited by the restriction sites which are

present in the gone. Some of these sites are defined, by way of example, in Figure 18.

Another fragment according to the invention is a fragment of at least 1000 bp which is derived from any region of the flbA gene and which preferably includes a restriction site or is capable of accommodating a restriction site.

Other nucleotide sequences of the invention are, for example, recombinant nucleic acids which comprise a nucleotide sequence such as those which have been described above, itself modified by the insertion of a cassette containing a marker, for example a gene for resistance to an antibiotic or a gene for resistance to a heavy metal such as described in Application FR 9406202, which was filed on 20/05/94.

Thus; a cassette for resistance to kanamycin can be inserted. Various techniques can be used in this context and reference is made, in particular, to the paper of Labigne A. et al. (J. of Bacteriology, Vol. 170, 1988, p. 1704-1708) and the paper of Labigne A. et al. (Res. Microbiol 1992, 143, 15-26).

The invention also relates to specific oligonucleotides from a previously defined nucleotide sequence, which oligonucleotides are characterized in that they possess one of the following sequences:

OLFlbA-1: ATGCCTCGAGGTCGAAAAGCAAGATC

OLF1bA-2: GAAATCTTCATACTGGCAGCTCCAGTC

OLF1bA-7: CGGGATCCGTGGTTACTAATGGTTCTAC

OLF1bA-8: CGGGATCCTCATGGCCTCTTCAGAGACC

According to another embodiment, the invention relates to an amino acid sequence from the FlbA protein of <u>H.pylori</u>, which sequence is characterized in that it is encoded by a nucleotide sequence such as previously defined.

A specific amino acid sequence from the FlbA protein of <u>H. pylori</u> is depicted in Figure 2.

Thus, within the scope of the invention, the <u>flbA</u> gene and the protein expressed by this gene can be of interest, in particular for employment in

20

immunogenic compositions or compositions used for vaccination.

The invention is also directed bacterial strains of Helicobacter pylori which possess 5 an aflagellate phenotype, which phenotype results from the mutation, by substitution, addition and/or deletion of bases or of a nucleotide fragment, of the abovedefined nucleotide sequence of the flbA gene involved in the regulation of the biosynthesis of the flagellar proteins of H. Dylori.

This modification of the flbA gene makes it possible to obtain a strain of the aflagellate type, that is which no longer expresses the FlaA and FlaB proteins and which profesably no longer expresses the proteins of the sheath.

According to one embodiment of this bacterial strain, the strain which is obtained additionally lacks the hook protein of H.pylori.

Preferably, a bacterial strain which meets the abovementioned criteria is characterized in that it is obtained from the strain N6, which was deposited in the NCIMB on 26 June 1992 under number NCIMB 40512.

By way of example, the invention relates to a recombinant aflagellate strain of H. pylori which is designated N5flbA- and was deposited in the NCIMB on 30 June 1995 under the No. NCIMB 40747.

Such aflagellate strains of H.pylori are of particular interest for employment in serology and, as a consequence, for the in-vitro detection of an infection due to H. pylori. These strains are advantageously of the recombinant type.

In particular, these strains exhibit the advantage of enabling an infection due to H.pylori to be detected in vitro in a specific and sensitive manner. In other words, the invention advantageously enables an infection due to H.pylori to be detected specifically while avoiding, in particular, "false-positive" results, for example with bacterial strains such as Salmonella or Campylobacter.

20

Given that the strains of H.pvlori of aflagellate type, which have thus been defined, also have other applications, for example may be employed in the preparation of vaccine compositions, there can interest in preparing recombinant be aflagellate bacterial strains which possess a second modification or mutation, for example an aflagellate bacterial strain can be prepared which is characterized in that it is additionally mutated in such a way that it produces an attenuated urease, or even no longer produces urgane, with the mutation consisting, example, of a mutation of the nucleotide sequence of one or more genes selected from among the genes ureA. ureB, ureC, ureD, urcE, ureF, ureG, uroH or ureI. The 15 urease structural genes, designated ureA, ureB, ureC and urcD of urease, have been described in publication (Labigne et al (1991) J. Bacteriol. 173: 1920-1931). The other genes have been described in Patent Application EP 0610322.

The bacterial strains of the invention may be employed as such or in extract form, and, in particular, the invention relates to a total bacterial strain extract which is obtained from the previously described strains.

25 Such a bacterial extract can be prepared by extracting with n-octyl glucoside. In this case, the preparation technique which is employed is that described by LELWALA-GURUGE J. (Scand. J. Infect. Dis. 1992, 24: 457-465).

30 Another bacterial extract can be obtained by extracting with PBS or glycine using the techniques described, respectively, by BAZILLOU M. ec al (Clin. Diagn. Lab. Immuno., 1994, 1: 310-317) and AGUIRRE P.M. (Eur. J. Clin. Microbiol. Infect. Dis., 1992, 35 634-639).

Within the scope of these applications, invention relates to a composition for the in-vitro detection of an infection due to H. pylori in a sample of biological fluid obtained from a patient,

particular in a sample of serum, which composition includes, as the active principle, a bacterial strain of the invention or a bacterial extract in accordance with the description given above.

The biological samples which are used may be of any type and can, in particular, be any type of biological fluid, such as serum, saliva or urine, for example.

In the same way, the techniques which are employed for the detection are any techniques which involve reactions of the immunological type, in particular of the antigen/antibody type. For example, use is made of techniques such as Western blot, ELISA, etc.

The invention also relates, therefore, to a method for the <u>in-vitro</u> detection of an infection due to <u>H.pylori</u> in a sample of biological fluid taken from a patient, in particular in a sample of serum, which method comprises the steps of:

- bringing the sample under test into contact

 20 with a bacterial strain according to the invention or

 with a bacterial extract as defined above.
- detecting an immunological reaction between
 the said bacterial strain and antibodies which are
 directed against <u>H. pylori</u> and which are present in the
 25 sample under test.

By way of example, an <u>in-vitro</u> detection on a biological sample in order to look for an infection due to <u>H.pylori</u> can be carried out by implementing the following steps:

- plates are covered with the antigen which is used for the detection and which may be a pure or recombinant protein or else an aflagellate strain or a bacterial extract, in particular an NOG (n-octyl glucoside) extract of the N6flbA- strain (by way of example, the quantity of extract might be 3 μg/ml or the quantity of antigen might be 2 μg/ml),
 - a range of negative and positive controls (the positive control being employed at differing dilutions) is used, and patient sera, which are diluted

30

35

to 1/100, are tested in parallel (volume deposited, 100 μ l),

- an incubation step is then carried out, for example at 37°C for one hour, which step is followed by several successive washings and by a further incubation, for example at 37°C for 1 hour, with a monoclonal conjugate (of the human IgG type labelled with peroxidase), which conjugate is employed at differing dilutions (for example at a dilution of 1/32000 in the case of an antigen and at a dilution of 1/64000 in the case of a bacterial extract), with the deposited volume being 100 μ 1,

- after the incubation with the monoclonal conjugate, several different washings are carried out (for Example 4) and the enzymic reaction is developed, in the dark and for 30 minutes, using "OPD + substrate". The enzymic reaction is then stopped by adding H₂SO₄, after which the optical densities, OD's, are read at 492 nm/620 nm.

The invention is furthermore directed to an immunogenic composition for obtaining antibodies against <u>H.pvlori</u>, which composition is characterized in that it includes, as the active principle, a bacterial strain according to the invention or an extract of this bacterial strain.

According to one particular embodiment of the invention, an immunogenic composition for obtaining antibodies against <u>H. Dylori</u> is characterized in that it includes an amino acid sequence from the FlbA protein.

Also included within the scope of the present invention is a vaccinating composition for obtaining antibodies which protect against an infection due to H. pylori, characterized in that it includes, as the active principle, a bacterial strain according to the invention or a bacterial extract according to the above definitions.

Another vaccinating composition for obtaining antibodies against an infection due to <u>H.pylori</u> is characterized in that it includes, as the active

10

20

25

30

principle, antigens of the urease type, in particular antigens encoded by the genes urea, urea, urea, urea, or ureand and a protein having an amino acid sequence as defined above.

The invention also relates to monoclonal antibodies or polyclonal sera which are directed against a
previously described amino acid acquence. These antibodies are obtained by techniques which are known per
se, in particular by immunizing an animal with the
chosen antigen, followed either by producing and
recovering the antibodies which are produced and
selecting those among them which specifically recognize
H. Dylori, or by preparing hybridomas, by fusing spleen
cells from the previously immunized animal with myeloma
cells, with these hybridomas then being cultured in
order to obtain monoclonal antibodies, which are
nelected on the basis of the specificity with which
they recognize the chosen H. Dylori antigen.

Other monoclonal antibodies or polyclonal sera according to the invention are directed against an aflagellate <u>H. Dylori</u> strain such as described in the preceding pages.

The invention furthermore relates to a composition for the <u>in vitro</u> detection of an infection due to <u>H.pylori</u> in a biological sample, which composition includes, as the active principle, monoclonal antibodies or a polyclonal serum which have been obtained against an <u>H.pylori</u> strain of the allagellate phenotype according to the invention.

The invention also relates to nucleotide sequences, as the active principle of a medicament, which encode amino acid sequences according to the invention, which amino acid sequences are able to induce an immunogenic response in an animal or in a patient. A technique for employing nucleotide sequences as medicaments has been described by DONNELY et al 1995, Nature Medic. 1(6), pp. 583-587.

Figure 1

15

1A: Restriction map of the plasmid pILL570 and of the mini transposon Tn3 containing the cassette of the gene for resistance to kanamycin.

5 1B: Linear restriction maps of the recombinant plasmids pSUS39 and pSUS207. The numbers which are shown correspond to the sizes of the restriction fragments, expressed in base pairs. H: HindIII; Bg: BglII. The presence of an asterisk indicates that the restriction site was modified during the cloning and that it is no longer recognized by the corresponding restriction

longer recognized by the corresponding restriction enzyme.

Figure 2: Nucleotide sequence of the <u>flbA</u> of <u>H.pvlori</u> and the deduced amino acid sequence, given in one-letter code.

Figure 3: Multiple alignment of the FlbA protein of H. Dvlori with five other members of the LcrD/FlbF family. CjFlbA: Campvlobacter jejuni FlbA; CcFlbF: Caulobacter crescentus FlbF; YpLcrD: Yersinia pestis

20 LerD; StlnvA: <u>Salmonella typhimurium</u> InvA; SfMxiA: <u>Shigella flexmeri</u> MxiA. The asterisks indicate the positions of the amino acida which are conserved in all the homologs of the LcrD/FlbF family; the dots indicate the positions of the amino acids which are conserved in

25 at least 5 out of the 6 homologous proteins; the conserved amino acid sequences which were used for synthesizing the degenerate oligonucleotides (OLFlbA-1 and OLFlbA-2) are underlined. Particular note should be taken of the degree of conservation of the N-terminal domain of these homologous proteins, which contrasts

with the degree of variability of the hydrophilic domain of the C-terminal region.

Figure 4: Diagrammatic depiction of the phylogenetic tree of six proteins belonging to the LcrD/FlbF family.

The proteins which are involved in regulating the expression of mobility, i.c. FlbA of <u>H.pylori</u> (HpFlbA) and of <u>Campylobacter jeiuni</u> (CjFlbA), and FlbF of <u>Caulobacter crescentus</u> (CcFlbF) form a branch which is distinct from that of the proteins involved in the

secretion of virulence proteins (InvA, MxiA and LcrD of Salmonella, Shigella and Yersinia, respectively). The numbers which are shown depict the relative evolutionary distance.

- Figure 5: Diagrammatic representation of the strategy which was followed for constructing the isogenic mutants of <u>H. Dvlori</u> strain N6, i.e. mutants in which the gene encoding the FlbA protein was inactivated by inserting a gene encoding for resistance to kanamycin.
- Figure 6: Analysis by immunoblotting (Western blot) of the proteins from an N6-(1)bA mutant using AK179 antiserum (3), which is specifically directed against flagella which have been purified from H.pylori: 1: N6flbA mutant; 2: flaA/flaB double mutant; 3: flaB (8)
- figures 7 to 11: Comparative results from the serology carried out on H.pvlori.

Figures 12 and 13: Extractions using the aflagellate strain N6flbA-: the extractions were carried out using 20 glycine, PRS or NOG.

I <u>Identification of the flbA dene and preparation of afladellate strains</u>

Among the proteins which are known to play a in regulating the expression of bacterial mobility, the proteins belonging to the recently identified LcrD/FlbF family, which include the LcrD protein of the bacteria of the genus Yereinia (6), the InvA protein of Salmonella (2), MxiA of Shigella (1), of <u>Caulobacter</u> crescentus (7) and LfbA Campylobacter jejuni (4), are protoins of interest. The LorD , InvA and Mxia proteins are involved in the regulation and/or the secretion of proteins which are associated with the virulence of the bacteria which express them, whereas the FlbF protein of Caulobacter Croscentus and the FlbA protein of Campylobacter jejuni are involved in regulating the biosynthesis of the flagella and therefore involved in regulating mobility. The homologs of the LcrD/FlbA family which are known to date possess very conserved domains, especially in the N-terminal part of these proteins, and it was therefore possible to use two of these conserved regions (MPGKQM, amino acids 151 to 156 of the LcrD protein of Yersinia) and MDGAMKF (amino acids 189 to 195 of LcrD) for defining two degenerate oligonucleotides (OLF1bA-1 OLFlbA-2, Table 1), which were synthesized and which have served as nucleotide primers in the gene amplification experiments which were carried out on the chromosomal DNA of Helicobacter pylori. In this way, it was possible to amplify a fragment of 130 base pairs (bp), and determination of its nucleotide sequence

demonstrated that this fragment encoded a segment of a protein which was very homologous to the proteins of the LcrD/FlbF family. This amplified fragment was then labelled radioactively and used as a probe to screen an H.pylori cosmid library.

This fragment corresponds to the sequence contained between nucleotides 575 and 707 of the sequence depicted in Figure 2.

One of the cosmids of the genomic library was encoding the LcrD/FlbF homolog identified as 10 H. bylori and was then subjected to a partial digestion with Sau3A so as to construct a mini library (200 subclones) of the cosmid in vector pILL570, containing inserted fragments possessing a size of between 2 and 5 (kilobases). Vactor pILL570 has been described in the 15 paper by Labigno A. et al (Institut Pasteur/Elsevier Paris 1992. Reg. Microbiol. 1992, 143, 15-26). Its restriction map is given in Figure 1A. These 200 clones were then hybridized to the 130 bp probe, and the clones which harboured plasmids pSUS39 and pSUS207 gave a positive hybridization. The linear restriction maps of these two recombinant plasmids are depicted in Figure 1B and demonstrate that the two inserts of these clones have overlapping sequences. Determination of the nucleotide sequences of these two inserts revealed that 2.5 neither of the two inserts contained the flbA gene in its entirety. The flbA gone of H. bylori, designated in this way due to its homology with the flbA gene of Campylobacter jejuni, corresponds to an open reading frame of 2196 nucleotides and encodes a protein having 30 a calculated molecular mass of 80.1 kilodaltons. The nucleotide sequence of flbA and the amino acid sequence of FlbA are given in Figure 2. Consensus sequences which are characteristic for promoter or terminator sequences have not been detected upstream and downstream of the open reading frame.

The FlbA protein exhibits similarities with the FlbA protein of Campylobacter jeiuni and the FlbF protein of Caulobacter crescentus, both of which are

25

30

involved in mobility (51.7% and 40.4% identity, respectively) whereas these percentages are lower with members of the LcrD/FlbP protein family which are not involved in mobility: 32.8% identity with LcrD from Yersinia, 30.5% with MxiA from Shigella and 29.3% with InvA from Salmonella. A multiple alignment of the amino acid sequences of these proteins with that of H.pylori FlbA is given in Figure 3. The most conserved regions of the homologs of the LcrD/FlbF family are located in the N-terminal part of the proteins.

The phylogenetic evolution of the proteins involved in mobility (FlbA and FlbF) and that of the proteins involved in regulating the expression and/or the secretion of proteins associated with virulence is depicted diagrammatically by a phylogenetic tree (Figure 4). Two distinct branches can be seen; H.pvlori FlbA belongs unambiguously to the branch corresponding to the regulatory proteins involved in the biosynthesis of the flagella.

20 Construction and characterization of isogenic mutants of H. pylori which are deficient in the synthesis of the FlbA protein.

A 1600 base pair fragment was amplified from plasmid pSUS39 using the oligonucleotides OLFlbA-7 and OLFlbA-8 (Table 1), each of which contains a BamHI restriction site at its 5' end. In its central region, this amplified fragment contains a unique HindIII restriction endonuclease site and was cloned into vector pSUS33, which is a derivative of plasmid pUC19 in which the HindIII site cituated in the multiple cloning site has been deleted. In order to obtain pSUS33, plasmid pUC19 was restricted with <u>Hind</u>III; the sticky ends resulting from this restriction were treated with Klenow enzyme and T4 DNA polymerase in order to produce blunt ends; the resulting fragment was religated with T4 DNA ligase and introduced into E.coli DH5x in order to produce pSUS33. The recombinant plasmid resulting from the integration of the 1600 base pair fragment into pSUS33 was designated pSUS40; it was

linearized with HindIII, its ends were blunt-ended and the Smal kanamycin cassette, which was derived from plasmid pILL600 (Labigne A. et al, 1988, J. Bact. 170, 1704-1708), was cloned into this unique site, resulting in placmid pSUS42. Plasmid pSUS42 was then introduced by electroporation into the "N6" strain of H.pvlori. The electroporation was carried out in accordance with the technique described by Ferrero R.L. et al (Journal of Bacteriology, July 1992, pp. 4212-4217, Vol. 174, No. 13). The transformants which were obtained after selecting on a selective medium containing kanamycin (25 µg/ml) were then characterized genotypically and phenotypically. Figure 5 shows a diagram of the procedure which was followed for the construction of mutants. Genotypic characterization of these mutants, by gene amplification and Southern hybridization, demonstrated that the genomes of the transformants which were resistant to kanamyoin contained the resistance gene inserted in the middle of the flbh gene and that there had therefore been an allelic replacement. by means of double crossing-over, of the wild-type copy of the flbA gene by the inactive flbA-Km copy, with the loss of the nucleotide sequences of the pSUS33 vector. Phonotypic characterization of the flbA mutants of H. <u>pylori</u> demonstrated that they were not furthermore, analysis of these mutants by electron microscopy revealed that there was a total absence of the flagellum elements and an absence of the flagellum sheath. The immunoblotting experiments (Wastern blots) which were carried out using antibodies directed against the proteins of the entire flagellum of H. pylori (Figure 6) demonstrated that two peptide bands corresponding to the flagellar subunits FlaA and FlaB were absent, as was a band corresponding to a polypeptide of an apparent mass of 90 kilodaltons, which is a protein which has recently been identified by O'Toole and collaborators (5) as being the hook protein (or anchoring protein) of the flagellum (5).

Taken as a whole, these results suggest that the FlbA protein of <u>H.Dvlori</u> is essential for the biosynthesis of all the flagellar structures and that inactivation of the gene encoding this protein results in complete cessation of the synthesis of any structure entering into the formation of the flagellum and not in interruption of the export of the constituents of these structures.

10 Table 1: Oligonucleotides employed in this study

	Oligo- nuclnotide	Position	Strand Nucleotide sequence

15	1)	HspAmalE	(HspA=13 kD) A sensitivity of 41% and a spaci- ficity of 36% were obtained on
20			the population termed population 1 of documented sera.
25	2)	N6flbA-	aflagellate strain of Helicobacter pylori 3 extractions were carried out: - n-Octyl glucoside - PBS - Glycine For the time being, the extraction with n-octyl glucoside (NOG)
30			appears to be the best.

corresponding wild-type strain

3) -NG

An extraction was carried out with n-octyl glucoside.

A second population of sera was employed (population II). This population consists of some one hundred sera which are well documented from the clinical, endoscopic, histological, bacteriological and anatomopathological points of view. It was this population II which was used to assess the performances of the different models under study. Five different populations were tested.

- 5 populations of tested scra:

- 300 ordinary sera (FNTS)
- 18 sera which were positive by WHITTAKER serology (CBMS)
- 92 well documented sera termed sera of population II
- 87 sera which were documented from the bacteriological and anatomopathological points of view and which were termed sera of population I.
- 23 sera exhibiting cross reactions:
 - 10 anti-Legionella positive sera
 - 10 anti-Chlamydia positive sera
 - 3 anti-Campylobacter positive scra

Two competing kits, which bibliographic studies indicated were effective, were tested in parallel.

- 2 tested commercial kits:

- Cobas Core (ROCHE)
- Pylori Stat (WHITTAKER)

- Results

The ordinary sera (FNTS) (Figures 8 to 11, Table 2)

- 300 sora were taken through the following models:
 - Hsp A malE
 - N6 flBA-
 - N6

The epidemiological studies give scroprevalences, in France, of between 20 and 25%. The distribution of 300 blood donor sera was studied and the prevalence of positivity was calculated for different threshold values in order to validate the threshold value which was previously defined using the CBMS serum library (WHITTAKER serology).

This study enables the different tests to be 10 compared using the same seroprevalence.

- The first 43 sera were also taken through the following models:
 - Cobas Core (ROCHE)
 - Pylori Stat (WHITTAKER)
- serology known as JLF serology (ELISA test, based on an aqueous extract of several bacterial strains)

The results are expressed in arbitrary units 20 and for different threshold values; a positive result is written as 1 and a negative result is written as 0.

On comparing these 43 sera in different tests, it can be observed that:

- the aflagellate strain N6flbA- and the Cobas

 Core test (Roche) give comparable seroprevalences of the order of 20%.
 - HspA gives a very low seroprevalence (7%), which suggests a lack of sensitivity in view of the subsequent results.
- the JLF serology appears to be very specific since the seroprevalence is only 14%, considering the subsequent results.
 - the Pylori Stat test (Whittaker) gives a high seroprevalence (29%), which might indicate a lack of specificity or a threshold value which is too low.

The sera which are positive by WHITTAKER serology (CBMS) (Table 3)

Three sera were found to be positive only with the Pylori Stat test (Whittaker). They were not confirmed using any other test.

It may be supposed that this result is due to this test lacking specificity. If the Cobas Core test (Roche), which is one of the best which is currently on the market, is taken as the reference, we can compare our different models in relation to Cobas Core.

- The aflagellate N6flbA- strain correlates perfectly with Cobas Core.
- The 3 sera which are negative with Cobas Core are also negative with N6flbA-
- The 15 sera which are positive with Cobas Core are also positive with NfflbA-.
 - The wild-type N6 strain gives the same results as the aflagellate strain.
- HspA also lacks sonnitivity since 9 Cobas Core-20 positive sera are negative with HspA.

The 3 sera which are negative with Cobes Core are also negative with HspA.

The sera of population II

92 sera were selected, with the sara dividing into 3 groups:

-34: dyspeptic patients
diagnosis of ulcer (duodenal or gastric)
by endoscopy and histology
presence of <u>Helicobacter pylori</u> by
culture and/or anatamopathologically; a
rapid urea test was also carried out.
This group will be termed Hp+/U+

-27: dyspeptic patients differential diagnosis of ulcer (gastritis etc.) by endoscopy and histology presence of Helicobacter bylori culture and/or anatamopathologically, a rapid ures test was also carried out. This group will be termed Hp+/U-

-31: patients which are or are not dyspeptic normal gastroduodenum by endoscopy and histology

absence of Helicobacter bylogi by

absence of <u>Helicopacter pylori</u> by

culture and anamatopathologically; a

rapid urea test was also carried out.

This group will be termed Hp-

The clinical, endoscopic, histological, bac-30 teriological and anatomopathological findings are indicated for each patient.

This well documented population enabled criteria of sensitivity and specificity to be defined.

- HpA: A substantial lack of sensitivity, as observed with population I, is still noticed.

The sensitivity is 59%, with a specificity of 100.

-N6flbA:	A sensitivity of 100% is confirmed for
	the n-octyl glucoside extract, with a
	specificity of 90%.
	This result is comparable to that
	obtained with the Roche Cobas Core test
	(98% sensitivity with a specificity of
	94%).
-N6:	On population II, the wild-type strain
	is entirely comparable to the
	aflagellate strain.
	None of the 31 negative sera is positive
	with the wild-type strain; no cross
	reaction due to the flagellum was
	detected with this population II.

The place of serology

Serology is placed at 2 levels:

- <u>Very sensitive</u> serology: for the purpose of detecting the presence of the bacterium in young subjects complaining of epigastric pains.
- If the serology turns out to be negative, the subject will not have to suffer endoscopy or a biopsy and another cause for his pains will be sought.
- Risk-specific serology: this involves demonstrating the risk of having a serious infection with Helicobacter pylori, that is an ulcer, a cancer or a gastric lymphoma (MALT lymphoma).
 - .- either using a molecule which is specific for the risk in question
- or using a risk-specific threshold
 (threshold value which is higher in subjects which are at risk than in subjects which are not at risk).

This specific serology can be employed to screen the general population and thus to detect cancers and lymphomas which are associated with Helicobacter pylori and which would not be detected because of a lack of symptoms. (Only subjects which complain of pain will consult a gastroenterologist).

The response to the sensitivity issue is good.

Correlation between the intensity of the gastritis and the antibody levels

The gastritis is defined by 3 parameters:

- Atrophy (represented by the first figure after 6); its intensity is marked from 1 to 4.
 - The global inflammation corresponds to infiltration with neutrophilic polynuclear cells and with monocytes; (represented by the second figure after the G). Its intensity is marked from 1 to 3.
- Activity corresponds to the number of neutrophilic polynuclear cells (represented by the third figure after the G); its intensity is marked from 0 to 3. Some folicular forms are marked F.

Normally, the following correlation can be observed:

The activity correlates very well with Helicobacter pylori.

The inflammation correlates well with <u>Helicobacter</u> pyloni.

The means of the titres observed in each group 20 have therefore been calculated in terms of these 3 parameters and their intensity.

Interpretation of the results:

Use of a t test makes it possible to demon-25 strate whether a difference between 2 observed means is significant or not with a 5% risk.

The hypothesis on which the t test is based is the equality of variances, demonstrated by an F test (Fisher test).

30 Since some variances are not equal, it is not therefore possible to compare all the means with each other.

By comparing the means, when possible, it has been possible to demonstrate whether the differences between the different groups are significant or not.

- Significant difference:

Between the means of "2" and "3" for HspA and NOG in the "Inflammation" group.

- Non-significant difference:

With regard to activity, no significant differences were domonstrated between the different intensity levels:

5 - <u>HspA</u>:

no significant difference between levels 0 and 2

0 and 3

1 and 2

1 and 3

10 2 and 3

- NOG:

no significant difference between levels 0 and 1

0 and 2

1 and 2

15 1 and 3

2 and 3.

It is nevertheless possible to observe a tendency for the titres to increase in dependence on the intensity of the gastritis:

- with regard to atrophy, the means double, for HspA and for the NOG extract of the aflagellate strain, when passing from level 1 to 2 and from level 2 to 3.
- with regard to inflammation, the means double when passing from level 1 to 2.

The numbers in each group are relatively low (in each case <30) for drawing conclusions with regard to statistically significant differences.

Sexa able to exhibit cross reactions

2 types of sera were employed.

20 sera (10 anti-Legionella + and 10 anti-Chlamydia +) being able to exhibit cross reactions with HspA, because these 3 bacteria possess heat shock proteins which are very akin to each other.

3 anti-Campylobacter positive sera, in order to demonstrate cross reactions with the flagellate strain N5 which would disappear with the aflagellate strain N5flbA-. It is very difficult to obtain anti-Campylobacter positive sera; this is the reason for there only being 3 sera.

HnpA does not exhibit any cross reaction, either with the 10 anti-Legionella positive sera or with the 10 anti-Chlamydia positive sera.

While some of these sera have positive titres of anti-<u>Helicobacter pylori</u> antibodies, both with the flagellate strain and with the aflagellate strain, the clinical context of these sera is not known.

CONCLUSION

HSDA malE

It is still not possible to use this molecule on its own since it also lacks sensitivity, but it could be of interest if it is associated with other molecules.

It nevertheless carries a risk of cross reactions due to the substantial conservation of these heat shock proteins between the different bacterial 10 species.

NSflbA-

This aflagellate variant appears to be of great interest; the sensitivity and specificity which were obtained with serum population II demonstrate a very favourable efficacy.

N5

15

20

For the time being, the flagellate strain appears to be of interest. However, the cross reactions relating to the flagellum have only been studied to a limited extent due to the difficulty of obtaining sera which are well documented with regard to <u>Campylobacter</u> serology.

· JLF test

A serological test based on an aqueous (PBS) extract of several atrains of <u>Helicobacter pylori</u> was developed. This test appears to be very efficacious.

A NOG extract of the aflagellate variant was used to test serum population I.

37 sera, which were documented only from the bacteriological and anatomopathological points of view, were tested with the aflagellate bacterial extract.

A serum is positive if the culture is positive or if the anatomopathology and the rapid urea test are positive.

A sexum is negative if the 3 tests (culture, anatomopathology and rapid urea test) are negative.

 λ sensitivity of 90.3% (28/31) is found together with a specificity of 71.4% (40/56).

Of 16 sera which are falsely positive using a first test, 9 are positive either using JLF serology or using the JLF Western blot, or using both of them.

Of the 3 sera which are falsely negative using 5 a first test, all 3 are negative either with JLF serology or with JLF Western blot, and one serum is negative with both the systems.

25

CLAIMS

- Nucleotide sequence which regulates the biosynthesis of the flagellar proteins of Helicobacter
 pvlori and is able to hybridize, under conditions of high stringency, with a probe corresponding to a nucleotide fragment from H.pvlori which has been amplified using two oligonucleotides having the following sequences:
- 10 OLFlba-1: <u>ATGCCTCGAGGTCGAAAAGCAAGATG</u>
 - OLFlbA-2: <u>GAANTCTTCATACTGGCAGCTCCAGTC</u>, or able to hybridize, under conditions of high stringency, with these oligonucleotides.
- Nucleotide sequence of the <u>flbA</u> gene which regulates the biosynthesis of the flagellar proteins of <u>Helicobacter pylori</u>, such as obtained by the steps of:
- screening a genomic library containing the chromosomal DNA of an <u>H.pylori</u> strain with a probe corresponding to a nucleotide fragment from <u>H.pylori</u>

 which has been amplified using two nucleotides having the following sequences:
 - OLFlbh-1: ATGCCTCGAGGTCGAAAAGCAAGATG
 - OLFlbA-2: <u>GNAATCTTCATACTGGCAGCTCCAGTC</u>, or able to hybridize, under conditions of high stringency, with these oligonucleotides.
 - recovering the DNA sequences which hybridize with the said probe.
 - subcloning the DNA sequences which have been obtained in an appropriate vector of the plasmid type and selecting those modified vectors which hybridize, under conditions of high stringency, with the probe corresponding to the DNA fragment from <u>H.pylori</u> which has been amplified using oligonucleotides OLFlbA-1 and OLFlbA-2,
- sequencing the DNA fragments contained in the plasmid vectors which hybridize with the abovementioned probe and determining the open reading frame contained in these fragments.

30

- 3. Nucleotide sequence according to Claim 1 or Claim 2, characterized in that it has the nucleotide sequence depicted in Figure 2.
- 4. Nucleotide sequence according to any one of Claims 1 to 3, characterized in that it encodes a protein having the amino acid sequence depicted in Figure 2 or an amino acid sequence possessing the same regulatory properties with regard to the biosynthesis of the flagellar proteins of <u>H.pylori</u> as does the abovementioned sequence.
- 5. Nucleotide sequence according to any one of Claims 1 to 5, which sequence is modified, by deletion, substitution or insertion of bases or of a fragment of a nucleotide sequence, such that the flbh gene is no longer expressed in a host cell or such that expression of the flbh gene in a host cell does not enable the flagella of H.pvlori to be biosynthesized and, where appropriate, does not enable the hook protein of H.pvlori to be synthesized.
- 20 6. Nucleotide sequence corresponding to a fragment of the <u>flbA</u> gene according to any one of Claims 1 to 4, characterized in that it is a fragment of at least 6 nucleotides, preferably of at least 100 nucleotides, which is derived from the <u>flbA</u> gene, preferably delimited by restriction sites which are present in the sequence of the <u>flbA</u> gene.
 - 7. Recombinant nucleic acid, characterized in that it comprises a nucleotide sequence according to any one of Claims 1 to 6, which sequence is modified by the insertion of a cassette containing a marker, for example a gene for resistance to an antibiotic, or a gene for resistance to a heavy metal.
- 8. Recombinant nucleic acid according to Claim 7, characterized in that the nucleotide sequence according to any one of Claims 1 to 6 is modified by the insertion of a cassette for resistance to kanamycin.
 - 9. Oligonucleotides, characterized in that they are specific for a sequence according to any one of

Claims 1 to 3 and in that they have one of the following sequences:

OLF1bA-1: ATCGTCGAGGTCGAAAAGCAAGATG

OLF1ba-2: GANATCTTCATACTGGCAGCTCCAGTC

OLF1bA-7: CGGGATCCGGGTTACTAATGGTTCTAC

OLF1bA-8: CGCGATCCTCATGGCCTCTTCAGAGACC

- 10. Amino acid cequence of the FlbA protein of <u>H.oylori</u>, characterized in that it is encoded by a nucleotide sequence according to either of Claims 1 and
- 10 2.

15

5

- 11. Amino acid sequence, characterized in that it is the FlbA protein of <u>H. pvlori</u>, having the sequence depicted in Figure 2, or in that it is a fragment of this protein which is recognized by antibodies directed against the FlbA protein.
- 12. <u>Helicobacter pylori</u> bacterial strain, characterized in that it has an aflagellate phenotype which results from the mutation, by substitution, addition and/or the deletion of bases or of a nucleotide frag-
- 20 ment, of the nucleotide sequence according to any one of Claims 1 to 3 of the <u>flbA</u> gene participating in the regulation of the biosynthesis of the flagellar proteins of <u>H.pvlori</u>.
 - 13. Bacterial strain according to Claim 12, charac-
- 25 terized in that it additionally lacks the hook protein of H.pylori.
 - 14. Recombinant bacterial strain according to Claim 12 or Claim 13, characterized in that it is obtained from the strain N6, which was deposited in the NCIMB on
- 30 26 June 1992 under the number NCIMS 40512.
 - 15. Recombinant bacterial strain according to either of Claims 12 and 14, characterized in that it is the strain N6flbA-, which was deposited in the NCIMB on 30 June 1995 under the number NCIMB 40747.
- 35 16. Bacterial strain according to any one of Claims 12 to 15, characterized in that it is additionally mutated so that it produces an attenuated urease or else no longer produces urease, the mutation consisting, for example, of a mutation of the nucleotide

sequence of one or more genes selected from among the genes <u>ureA</u>, <u>ureB</u>, <u>u</u>

- 17. Bacterial extract, characterized in that it is an extract of bacterial strains according to any one of Claims 12 to 15.
 - 15. Bacterial extract according to Claim 17, characterized in that it is obtained after extracting with n-octyl glucoside.
- 10 19. Bacterial extract according to Claims 17, characterized in that it is obtained after extracting with PBS or with glycine.
 - 20. Composition for the in vitro detection of an infection due to <u>H. pylori</u> in a sample of biological
- 15 fluid from a patient, in particular in a sample of serum, which composition includes, as the active principle, a bacterial strain according to any one of Claims 12 to 15 or a bacterial extract according to any one of Claims 17 to 19.
- 20 21. Method for the <u>in vitro</u> detection of an infection due to <u>H.pvlori</u> in a sample of biological fluid from a patient, in particular in a sample of scrum, which method comprises the steps of:
- bringing the sample under test into contact with a bacterial strain according to any one of Claims 12 to 15, or with a bacterial extract according to any one of Claims 17 to 19,
 - detecting an immunological reaction between the said bacterial strain and antibodies which are
- 30 directed against <u>H.pylori</u> and which are present in the sample under test.
 - 22. Immunogenic composition for obtaining antibodies against <u>H.pylori</u>, characterized in that it includes, as the active principle, a bacterial strain
- according to any one of Claims 12 to 16 or a bacterial extract according to any one of Claims 17 to 19.
 - 23. Immunogenic composition for obtaining antibodies against <u>H.pvlori</u>, characterized in that it

includes an amino acid sequence according to either of Claims 10 and 11.

- 24. Vaccinating composition for obtaining protective antibodies against an infection due to <u>H. pylori</u>, characterized in that it includes, as the active principle, a bacterial strain according to any one of Claims 12 to 16 or a bacterial extract according to any one of Claims 17 to 19.
- 25. Vaccinating composition for obtaining anti10 bodies against an infection due to <u>H.pylori</u>,
 characterized in that it includes, as the active
 principle, antigens which are of the urnase type or
 which participate in the urease activity of <u>H.pylori</u>,
 in particular antigens encoded by the genes <u>MICA</u>, <u>ureB</u>,
- 15 <u>ureC</u> or <u>ureD</u> and a protein having an amino acid sequence according to either of Claims 10 and 11.
 - 26. Monoclonal antibodies or polyclonal serum which is/are directed against an amino acid sequence according to either of Claims 10 and 11.
- 20 27. Monoclonal antibodies or polyclonal serum which is/are directed against an <u>H.pylori</u> strain according to any one of Claims 12 to 15.
 - · 28. Composition for the <u>in vitro</u> detection of an infection due to <u>H. pylori</u> in a biological sample, which
- 25 composition includes, as the active principle, monoclonal antibodies or a polyclonal serum which is/are obtained against an <u>H. pylori</u> strain of the aflagellate phenotype according to any one of Claims 12 to 15.
- 30 29. Use of the nucleotide sequences according to any one of Claims 1 to 9 for preparing immunogenic compositions for obtaining antibodies against <u>H. pylori</u>.

 30. Kit for diagnosing antibodies of patients infected with <u>H. pylori</u>, which kit includes a bacterial
- 35 extract according to any one of Claims 15 to 19 and reagents which are required for demonstrating a reaction of the antigen/antibody type.

ABSTRACT

The present application relates to nucleotide sequences which regulate the biosynthesis of the flagella proteins <u>Helicobacter bylori</u>, to the proteins encoded by these sequences and to aflagellate bacterial strains. The invention also relates to the use of these means for detecting an infection due to <u>H.pylori</u> or for protecting against such an infection.

ATTORNEY	DOCKET	NO:

DECLARATION AND POWER OF ATTORNEY

As a below named inventor, I hereby declare that: my residence, post office address and citizenship are as stated below next to my name; that I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

CLONING AND CHARACTERIZATION OF THE FIBA GENE OF H. PYLORI

PRODUCTION OF AFLAGELIATE STRAINS

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, §1.56(a).

I hereby claim foreign priority benefits under Title 35, United States Code, §119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

COUNTRY	APPLICATION NUMBER	DATE OF FILING	PRIORITY CLAIMED UNDER 35 U.S.C. 119
FRANCE	95:08068	04/07/1995	XYES DNO
			DYES DNO

I hereby claim the benefit under Title 35, United States Code, §120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, §1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

APPLICATION NUMBER DATE OF FILING STATUS (Patented, Pending, Abandoned)

I hereby appoint the following attorneys to prosecute this application and transact all business in the Patent and Trademark Office connected therewith: Finnegan, Henderson, Farabow, Garrett and Dunner, Reg. No. 22,540; Douglas B. Henderson, Reg. No. 20,291; Ford. F. Farabow, Jr., Reg. No. 20,630; Arthur S. Garrett, Reg. No. 20,338; Donald R. Dunner, Reg. No. 19,073; Brian G. Brunsvold, Reg. No. 22,593; Tipton D. Jennings, IV, Reg. No. 20,645; Jerry D. Voight, Reg. No. 23,020; Laurence R. Hefter, Reg. No. 20,827; Kenneth E. Payne, Reg. No. 23,098; Herbert H. Mintz, Reg. No. 26,691; C. Larry O'Rourke, Reg. No. 26,014; Albert J. Santorelli, Reg. No. 22,610; Michael C. Elmer, Reg. No. 25,857; Richard H. Smith, Reg. No. 20,609; Stephen L. Peterson, Reg. No. 26,325; John M. Romary, Reg. No. 26,331; Bruce C. Zotter, Reg. No. 27,680; Dennis P. O'Reilley, Reg. No. 27,932; Allen M. Sokal, Reg. No. 26,695; Robert D. Bajefsky, Reg. No. 25,387; Richard L. Stroup, Reg. No. 28,478; David W. Hill, Reg. No. 28,220; Thomas L. Irving, Reg. No. 28,619; Charles E. Lipsey, Reg. No. 28,165; Thomas W. Winland, Reg. No. 27,605; Basil J. Lewris, Reg. No. 28,818; Robert J. Gaybrick, Reg. No. 27,890; Martin I. Fuchs, Reg. No. 28,508; E. Robert Yoches, Reg. No. 30,120; Stephen J. Rosenman, Reg. No. 29,209; Barry W. Graham, Reg. No. 29,924; Thomas H. Jenkins, Reg. No. 30,857; and

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.
